To solve linear programming using R studio, we need to install lpsolve package

Install.packages("lpsolve")

PRACTICAL 1

GRAPHICAL METHOD USING R PROGRAMMING

```
# R Program
#Find a geometrical interpretation and solution as well for the following LP problem
#Max z= 3x1 + 5x2
#subject to constraints:
#x1+2x2<=2000
#x1+x2<=1500
#x2<=600
#x1,x2>=0

# Load lpSolve
require(lpSolve)

## Set the coefficients of the decision variables -> C of objective function
C <- c(3,5)

# Create constraint martix B
A <- matrix(c(1, 2,
        1, 1,
        0, 1
), nrow=3, byrow=TRUE)

# Right hand side for the constraints
B <- c(2000,1500,600)
```

Eram Khan
Roll no -524

```
# Direction of the constraints

constranints_direction <- c("<=", "<=", "<=")

# Create empty example plot

plot.new()

plot.window(xlim=c(0,2000), ylim=c(0,2000))

axis(1)

axis(2)

title(main="LPP using Graphical method")

title(xlab="X axis")

title(ylab="Y axis")

box()

# Draw one line

segments(x0 = 2000, y0 = 0, x1 = 0, y1 = 1000, col = "green")

segments(x0 = 1500, y0 = 0, x1 = 0, y1 = 1500, col = "green")

segments(x0 = 0, y0 = 0, x1 = 600, y1 = 0, col = "green")

# Find the optimal solution

optimum <- lp(direction="max",

        objective.in = C,

        const.mat = A,

        const.dir = constranints_direction,

        const.rhs = B,

        all.int = T)

# Print status: 0 = success, 2 = no feasible solution

print(optimum$status)

# Display the optimum values for x1,x2

best_sol <- optimum$solution

names(best_sol) <- c("x1", "x2")
```

Eram Khan
Roll no -524

print(best_sol)

Check the value of objective function at optimal point

print(paste("Total cost: ", optimum$objval, sep=""))

File Edit View Insert Cell Kernel Widgets Help Trusted Python 3

Use SciPy to solve the resource allocation problem stated as follows:

Max z= 20x1 + 12x2 +40x3 + 25x4 ....(profit)

subjected to:

```
x1 + x2 + x3 + x4 <= 50  -------------(manpower)

3x1 + 2x2 + x3    <= 100 -------------(material A)

       x2 + 2x3   <= 90  -------------(material B)

    x1, x2, x3, x4 >= 0
```

In [12]:
```python
from scipy.optimize import linprog
```

In [13]:
```python
obj = [-20, -12, -40, -25]      #profit objective function
```

In [14]:
```python
lhs_ineq = [[1, 1, 1, 1],  # Manpower
...         [3, 2, 1, 0],  # Material A
...         [0, 1, 2, 3]]  # Material B
```

In [15]:
```python
rhs_ineq = [ 50,  # Manpower
...         100,  # Material A
...          90]  # Material B
```

In [16]:
```python
opt = linprog(c=obj, A_ub=lhs_ineq, b_ub=rhs_ineq,
...              method="revised simplex")
```

In [17]:
```python
opt
```

Out[17]:
```
     con: array([], dtype=float64)
     fun: -1900.0
 message: 'Optimization terminated successfully.'
     nit: 2
   slack: array([ 0., 40.,  0.])
  status: 0
 success: True
       x: array([ 5.,  0., 45.,  0.])
```

The result tells you that the maximal profit is 1900 and corresponds to x_1 = 5 and x_3 = 45. It's not profitable to produce the second and fourth products under the given conditions. You can draw several interesting conclusions here:

The third product brings the largest profit per unit, so the factory will produce it the most.

The first slack is 0, which means that the values of the left and right sides of the manpower (first) constraint are the same. The factory produces 50 units per day, and that's its full capacity.

The second slack is 40 because the factory consumes 60 units of raw material A (15 units for the first product plus 45 for the third) out of a potential 100 units.

The third slack is 0, which means that the factory consumes all 90 units of the raw material B. This entire amount is consumed for the third product. That's why the factory can't produce the second or fourth product at all and can't produce more than 45 units of the third product. It lacks the raw material B.

opt.status is 0 and opt.success is True, indicating that the optimization problem was successfully solved with the optimal feasible solution
